Integrating Rhizoma Perennial Peanut Into Grazing Systems

Lynn Sollenberger, Jose Dubeux, Liza Garcia, Erin Stenklyft, Param Aryal, Miguel Castillo, Ann Blount, Katie Cooley, and Kim Mullenix University of Florida Agronomy Department

Overview

• Perennial peanut is a great hay crop

• Does it fit in grazed pastures?

Overview

- Why it may
 - -Greater forage quality and animal performance than grass
 - Fixes nitrogen to avoid/reduce need for N fertilizer
 - Peanut is competitive with aggressive grasses, spreads into new areas of grass, and survives for a very long time under grazing

Overview

 Vision – a grazed peanut-grass pasture that requires no nitrogen fertilizer inputs

How do we get there?

 Identify or develop varieties that are well suited for use in grazed pasture

• Define viable methods of establishment

 Document potential increases in animal performance from including peanut Identify or develop varieties that are well suited for use in grazed pasture

• Do rhizoma peanut types vary in growth characteristics that relate to grazing tolerance?

Do growth characteristics matter? Ecoturf vs.
Florigraze

Tito

Chico

Characteristics of Several Rhizoma Peanut Lines

| Peanut Line | Height at harvest (inches) | Yield (tons/acre/year) | Below-ground biomass (tons/acre) |
|-------------|-------------------------------|---------------------------|--|
| Chico | 6 | 4.4 | 3.17 |

• Do rhizoma peanut types vary in growth characteristics that relate to grazing tolerance?

Do growth characteristics matter? Ecoturf vs.
Florigraze

A Case Study – Florigraze vs. Ecoturf

 Previous research showed that Florigraze is very tolerant of grazing but long-term overgrazing causes stand decline.

• What happens with lower-growing types?

Sward Characteristics Under Hay Management (10-wk regrowth)

| Cultivar/ Germplasm | | Bulk density (lb/acre/inch) |
|------------------------|----|--------------------------------|

Persistence

| Frequency | Percentage | Rhizome-root |
|-----------|------------|--------------|
| (wk) | peanut | mass |
| | (%) | (tons/acre) |
| 1 | 90 | 7.3 (+0.66) |
| 4 | 92 | 8.6 (+0.49) |
| 7 | 90 | 8.2 (+1.14) |

Conclusions

- Ecoturf responds to grazing very differently than Florigraze.
- Short growth habit and a lot of leaf close to soil surface under heavy grazing reduces potential negative impact on stored carbohydrates.
- Ecoturf shows excellent promise for use in grazed pasture.
- If we want peanut types that are successful under grazing, we need to select ones built for grazing.

How do we get there?

 Identify or develop varieties that are well suited for use in grazed pasture

• Define viable methods of establishment

 Document potential gains in animal performance from including peanut

Strip-planting of perennial peanut

No-till (herb. in fall + mowing in spring)

Hay production

1 hour after start of grazing

What did we learn?

- Seedbed preparation
 - Peanut can establish successfully in a range of conditions;
 - shoot emergence generally better in prepared seedbed; end of Year 1 cover better with no-till likely due to less weed competition

- Weed control
 - Imazapic or imazapic plus 2,4-D greatly improve establishment success; better light environment for new RP shoots

What did we learn?

- Variety selection
 - Lower growing types or those that can adapt to close defoliation are favored;
 - good success with Ecoturf; it performed better than Florigraze and Peace when strip planted
- Defoliation management
 - Cattle are attracted to planted strips and graze peanut very hard;
 - use of strip-planted fields for hay recommended for 2 yr to allow peanut to establish and start to spread into surrounding grass before grazing

 What about planting peanut and grass at the same time vs. planting peanut in strips with grass or alone?

Treatments

- Peanut planted alone
- Peanut planted simultaneously with bahiagrass seed
- Peanut planted in tilled strips in existing bahiagrass pastures

October – Year of Planting

| Treatment | Peanut shoot | Peanut below ground | Peanut total weight |
|-----------------|-----------------|---------------------------|------------------------|
| | | lb/acre | |
| Together | 460 | 410 | 870 |
| | | | |
| Peanut alone | 980 | 760 | 1740 |
| Peanut in strip | 1240 | 940 | 2180 |

Do Year 1 differences in shoot and below-ground mass continue to be evident in the year after planting?

October – Year after Planting

| Treatment | PeanutPeanutshootbelowground | | Peanut total weight |
|-----------------|------------------------------|---------|------------------------|
| | | lb/acre | |
| Together | 610 | 1625 | 2240 |
| | | | |
| Peanut alone | 2130 | 6100 | 8230 |
| Peanut in strip | 1640 | 5000 | 6740 |

Conclusions

- Ecoturf establishes well when planted in pure stand in a prepared seedbed or when strip planted into bahiagrass.
- Planting Ecoturf and bahiagrass at the same time is not an optimal management practice.
- If planting a new area and a bahia-Ecoturf mixture is desired:
 - Establish Ecoturf in pure stand
 - Control grass and weeds for at least the year of planting
 - Later, stop grass herbicide applications and a bahiagrass-peanut mixture will form

Planting date effects on establishment of four peanut varieties

How do we get there?

 Identify or develop varieties that are well suited for use in grazed pasture

• Define viable methods of establishment

 Document potential gains in animal performance from including peanut

Grazing study

| Warm-season | Cool-season |
|-----------------------------|----------------------------|
| Fertilized bahiagrass = 100 | Cool-season grass + 100 lb |
| lb N per acre (BGN) | N/acre |
| Unfertilized bahiagrass | Cool season grass-legume |
| pastures (BG) | mixture + 30 lb N/acre |
| Bahiagrass-rhizoma peanut | Cool season grass-legume |
| mixture (BG-RP) | mixture + 30 lb N/acre |

Animal performance (averages over two years)

| | Stocking rate (steer/ac) | Average daily gain (lb/hd/d) | Gain per acre (Ib/ac/yr) |
|--------------|--------------------------------|------------------------------------|--------------------------------|
| BG | 1.42 | 1.11 | 429 |
| BGN | 1.54 | 1.12 | 436 |
| BG-RP | 1.30 | 1.40 | 501 |

The legume system with 30 lb N/acre/year produced approximately 70 lb of additional liveweight/acre/year. Liza Garcia, unpublished data

NRCS EQIP Program

• New cost share program by NRCS to strip-plant rhizoma peanut into bahiagrass pastures (512 is the code for the EQIP practice).

They provide \$172/acre of solid strip. So, if you are covering 50% of the land area with peanut strips, you would get \$86/acre.

• Exploring a cost-share program with FDACS, but there is nothing final in that regard.

Take-home Messages

- Lower-growing or highly adaptive varieties are likely better options for grazing
 - Assume a more prostrate growth habit when grazed closely
 - –Maintain leaf close to soil surface to speed regrowth and minimize use of reserves

Take-home Messages

- Establishment management is key to achieving productive grass-legume mixtures
 - -Timing of planting
 - -Managing defoliation after planting
 - -Controlling competition from other plants

Take-home Messages

 Rhizoma peanut-bahiagrass pastures plus coolseason forages can produce more animal product per acre with less N fertilizer than grass alone
